Back Propagation & FF Coding

800

1. For the below feed-forward neural network architecture obtain the following weights after 1st Back Propagation iteration (epoch): [ignore the biases change during backpropagation]

inputs	L1-Weights	L1-Biases	L2-Weights	L2-Biases	L3-Weights	L3-Biases
$\begin{bmatrix} 0.3 \\ 0.5 \\ 0.8 \end{bmatrix}$	$\begin{bmatrix} 0.1 & 0.2 & 0.2 \\ 0.4 & 0.1 & 0.2 \\ 0.2 & 0.3 & 0.1 \end{bmatrix}$	$\begin{bmatrix} 0.2 \\ 0.2 \\ 0.1 \end{bmatrix}$	$\begin{bmatrix} 0.1 & 0.2 & 0.2 \\ 0.4 & 0.1 & 0.2 \end{bmatrix}$	$\begin{bmatrix} 0.1 \\ 0.4 \end{bmatrix}$	$\begin{bmatrix} 0.5 & 0.1 \\ 0.5 & 0.5 \end{bmatrix}$	$\begin{bmatrix} 0.5 \\ 0.3 \end{bmatrix}$

● Activation Functions:  $\begin{cases} \text{L1: Relu} \\ \text{L2: Tanh} \\ \text{L3: Sigmoid} \end{cases}$ 
 ● Loss Function: MSE
 ● Optimizer: GD

2. As you saw in the previous session, the designed model **could not predict** the input image correctly. Change the code and Design the **network** using **Dense layers** so that it can classify the input image (seven.png) correctly.
